

Theorem (Correctness)

If e is a program parameterized by an Authentikit implementation, i.e.,

$$\vdash e : \forall \text{auth}, m. \text{Authentikit auth } m \rightarrow m \tau$$

then if

e instantiated with **Prover** produces a proof p and returns v

then

- e instantiated with **Verifier** accepts p and returns v and
 - e instantiated with **Ideal** returns v as well.
- 

Summary

- **Authentikit** is a library for implementing secure and correct ADSs generically.
- Two **logical-relations models** and a proof of security and correctness of the Authentikit module-functor construction.
 - We verify several **optimizations**.
 - We show how to **safely link** manually verified code with code automatically generated using Authentikit.
- Full mechanization in the Rocq theorem prover.

Reminder

STLC: terms can depend on terms,

$$\frac{\Gamma, x : \sigma \vdash e : \tau}{\Gamma \vdash \lambda x . e : \sigma \rightarrow \tau}$$

System F: terms can depend on types,

$$\frac{\Theta, \alpha \mid \Gamma \vdash e : \tau}{\Theta \mid \Gamma \vdash \Lambda \alpha . e : \forall \alpha . \tau}$$

System F_ω: types can depend on types,

$$\frac{\Theta \vdash \tau \equiv \sigma \quad \Theta \mid \Gamma \vdash e : \sigma}{\Theta \mid \Gamma \vdash e : \tau}$$

$$\frac{}{\Theta \vdash (\lambda \alpha . \tau) \sigma \equiv \tau[\sigma/\alpha]}$$

The $F_{\omega, \mu}^{\text{ref}}$ language

$\kappa ::= \star \mid \kappa \Rightarrow \kappa$

(kinds)

$\tau ::= \alpha \mid \lambda \alpha : \kappa . \tau \mid \tau \tau \mid c$

(types)

$c ::= \dots \mid \times \mid + \mid \rightarrow \mid \text{ref} \mid \forall_{\kappa} \mid \exists_{\kappa} \mid \mu_{\kappa}$

(constructors)

The $F_{\omega, \mu}^{\text{ref}}$ language

$\kappa ::= \star \mid \kappa \Rightarrow \kappa$

(kinds)

$\tau ::= \alpha \mid \lambda \alpha : \kappa . \tau \mid \tau \tau \mid c$

(types)

$c ::= \dots \mid \times \mid + \mid \rightarrow \mid \text{ref} \mid \forall_{\kappa} \mid \exists_{\kappa} \mid \mu_{\kappa}$

(constructors)

$v ::= \dots \mid \text{rec } f x = e \mid \Lambda e \mid \text{pack } v$

(values)

$e ::= \dots \mid \text{hash } e$

(expressions)

The $F_{\omega, \mu}^{\text{ref}}$ language

$\kappa ::= \star \mid \kappa \Rightarrow \kappa$ (kinds)

$\tau ::= \alpha \mid \lambda \alpha : \kappa . \tau \mid \tau \tau \mid c$ (types)

$c ::= \dots \mid \times \mid + \mid \rightarrow \mid \text{ref} \mid \forall_{\kappa} \mid \exists_{\kappa} \mid \mu_{\kappa}$ (constructors)

$v ::= \dots \mid \text{rec } f x = e \mid \Lambda e \mid \text{pack } v$ (values)

$e ::= \dots \mid \text{hash } e$ (expressions)

We write, e.g., $\forall \alpha : \kappa . \tau$ to mean $\forall_{\kappa} (\lambda \alpha : \kappa . \tau)$ and $\tau_1 \times \tau_2$ for $\times \tau_1 \tau_2$

Authentikit in $F_{\omega, \mu}^{\text{ref}}$

```
module type AUTHENTIKIT = sig
  type 'a auth
  type 'a auth_computation

  val return : 'a -> 'a auth_computation
  val bind   : 'a auth_computation ->
    ('a -> 'b auth_computation) ->
    'b auth_computation

  module Serializable : sig
    type 'a evidence

    (* ... *)

  end

  val auth   : 'a Serializable.evidence -> 'a -> 'a auth
  val unauth : 'a Serializable.evidence ->
    'a auth -> 'a auth_computation
end
```

$\text{AUTHENTIKIT} \triangleq \exists \text{auth}, m : \star \Rightarrow \star. \text{Authentikit auth } m$

$\text{Authentikit} \triangleq \lambda \text{auth}, m : \star \Rightarrow \star. \\ (\forall \alpha : \star. \alpha \rightarrow m \alpha) \times \\ (\forall \alpha, \beta : \star. m \alpha \rightarrow (\alpha \rightarrow m \beta) \rightarrow m \beta) \times \\ \vdots \\ (\forall \alpha : \star. \text{evidence } \alpha \rightarrow \alpha \rightarrow \text{auth } \alpha) \times \\ (\forall \alpha : \star. \text{evidence } \alpha \rightarrow \text{auth } \alpha \rightarrow m \alpha)$

“F-ing” the module

Collision-free reasoning

To define our models, we define **Collision-Free Separation Logic** (CF-SL),

$$\text{wp } e \{ \Phi \}$$

that is expressive enough to state and prove security and correctness.

CF-SL statements hold “up to” hash collision.

CF-SL

CF-SL satisfies all the standard weakest precondition rules but introduces a resource $\text{hashed}(s)$ such that

$$\frac{}{\text{wp } \text{hash } s \{v. v = H(s) * \text{hashed}(s)\}}$$

and

$$\frac{\text{collision}(s_1, s_2)}{\text{hashed}(s_1) * \text{hashed}(s_2) \vdash \text{False}}$$

$$\llbracket \text{m} \rrbracket \triangleq \lambda A, (v_1, v_2). \forall p. \{\text{isProof}(p)\} v_1 p \sim v_2 () \{Q_{\text{post}}\}$$

Verifying Authentikit implementations

Security

$$\llbracket \text{auth} \rrbracket \triangleq \lambda A, (v_1, v_2). \exists a, t. v_1 = H(\text{serialize}_t(a)) * A(a, v_2) * \text{hashed}(\text{serialize}_t(a))$$

$$\llbracket \text{m} \rrbracket \triangleq \lambda A, (v_1, v_2). \forall p. \{\text{isProof}(p)\} v_1 \ p \sim v_2 \ () \ \{Q_{\text{post}}\}$$

Correctness

$$\llbracket \text{m} \rrbracket \triangleq \lambda A, (v_1, v_2, v_3). \forall p. \{\text{isProphProof}(p)\} v_1 \ () \sim v_2 \ p \sim v_3 \ () \ \{Q'_{\text{post}}\}$$

Verifying Authentikit implementations

Security

$$\llbracket \text{auth} \rrbracket \triangleq \lambda A, (v_1, v_2). \exists a, t. v_1 = H(\text{serialize}_t(a)) *$$
$$\llbracket \text{m} \rrbracket \triangleq \lambda A, (v_1, v_2). \forall p. \{\text{isProof}(p)\} v_1 p \sim v_2 ()$$

```
module Prover : AUTHENTIKIT =  
  (* ... *)  
  
  let unauth evi (a, _) p () =  
    let s = evi a in  
    resolve p to s;  
    ([s], a)  
  
end
```

Correctness

$$\llbracket \text{m} \rrbracket \triangleq \lambda A, (v_1, v_2, v_3). \forall p. \{\text{isProphProof}(p)\} v_1 () \sim v_2 p \sim v_3 () \{Q'_{\text{post}}\}$$

Security proof

The main work is to show

$$\llbracket \text{Authentikit auth } m \rrbracket (\text{Authentikit}_V, \text{Authentikit}_I)$$

The challenging part is finding the right interpretation of the type variables.

$$\llbracket \text{auth} \rrbracket (A)(v_1, v_2) \triangleq \exists a, t. v_1 = \text{hash}(\text{serialize}_t(a)) * A(a, v_2) * \text{hashed}(\text{serialize}_t(a))$$

$$\llbracket m \rrbracket (A)(v_1, v_2) \triangleq \forall p. \{ \text{isProof}(p) \} v_1 p \sim v_2 () \{ Q_{\text{post}} \}$$

$$Q_{\text{post}}(u_1, u_2) \triangleq u_1 = \text{None} \vee (\exists a_1, p'. u_1 = \text{Some}(p', a_1) * \text{isProof}(p') * A(a_1, u_2))$$

Optimizations of Authentikit

- Proof accumulator
- Proof-reuse buffering
- Heterogeneous buffering
- Stateful buffering

```
module Verifier : AUTHENTIKIT =
  type 'a auth_computation =
    pfstate -> ['Ok of pfstate * 'a | `ProofFailure]

  (* ... *)

  let unauth evi h pf =
    match Map.find_opt h pf.cache with
    | None ->
      match pf.pf_stream with
      | [] -> `ProofFailure
      | p :: ps when hash p = h ->
        match evi.deserialize p with
        | None -> `ProofFailure
        | Some a ->
          `Ok ({pf_stream = ps;
                cache = Map.add h p pf.cache}, a)
      | _ -> `ProofFailure
    | Some p ->
      match evi.deserialize p with
      | None -> `ProofFailure
      | Some a -> `Ok (pf, a)

  end
```

Manual client proofs

The naïve implementation of Authentikit does not emit optimal proofs, e.g.,

$\text{lookup}([R, L], t_0) = ([(h_1, h_2), (h_5, h_6), s_5], s_5)$

Instead, we can manually implement and “semantically type” the optimal strategy:

$\llbracket \text{path} \rightarrow \text{auth tree} \rightarrow m \text{ (option string)} \rrbracket (\text{fetch}_V, \text{fetch}_I)$

Ablation study
